# 1 What ExomeDepth does and tips for QC

### 1.1 What ExomeDepth does and does not do

ExomeDepth uses read depth data to call CNVs from exome sequencing experiments. A key idea is that the test exome should be compared to a matched aggregate reference set. This aggregate reference set should combine exomes from the same batch and it should also be optimized for each exome. It will certainly differ from one exome to the next.

Importantly, ExomeDepth assumes that the CNV of interest is absent from the aggregate reference set. Hence related individuals should be excluded from the aggregate reference. It also means that ExomeDepth can miss common CNVs, if the call is also present in the aggregate reference. ExomeDepth is really suited to detect rare CNV calls (typically for rare Mendelian disorder analysis).

The ideas used in this package are of course not specific to exome sequencing and could be applied to other targeted sequencing datasets, as long as they contain a sufficiently large number of exons to estimate the parameters (at least 20 genes, say, but probably more would be useful). Also note that PCR based enrichment studies are often not well suited for this type of read depth analysis. The reason is that as the number of cycles is often set to a high number in order to equalize the representation of each amplicon, which can discard the CNV information.

### 1.2 Useful quality checks

Just to give some general expectations I usually obtain 150-280 CNV calls per exome sample (two third of them deletions). Any number clearly outside of this range is suspicious and suggests that either the model was inappropriate or that something went wrong while running the code. Less important and less precise, I also expect the aggregate reference to contain 5-10 exome samples. While there is no set rule for this number, and the code may work very well with fewer exomes in the aggregate reference set, numbers outside of this range suggest potential technical artifacts.

## 2 Create count data from BAM files

#### 2.1 Count for the autosomes

Firstly, to facilitate the generation of read count data, exon positions for the hg19 build of the human genome are available within ExomeDepth. This exons.hg19 data frame can be directly passed as an argument of getBAMCounts (see below).

```
> library(ExomeDepth)
> data(exons.hg19)
> print(head(exons.hg19))
  chromosome start
                     end
                                    name
           1 12011 12058 DDX11L10-201_1
1
2
           1 12180 12228 DDX11L10-201_2
3
           1 12614 12698 DDX11L10-201_3
4
           1 12976 13053 DDX11L10-201_4
5
           1 13222 13375 DDX11L10-201_5
6
           1 13454 13671 DDX11L10-201_6
```

To generate read count data, the function getBamCounts in ExomeDepth is set up to parse the BAM files. It generates an array of read count, stored in a GenomicRanges object. It is a wrapper around the function countBamInGRanges.exomeDepth which is derived from an equivalent function in the exomeCopy package. You can refer to the help page of getBAMCounts to obtain the full list of options. An example line of code (not evaluated here) would look like this:

my.bam is a set character vector of indexed BAM files. fasta is the reference genome in fasta format (only useful if one wants to obtain the GC content). exons.hg19 are the positions and names of the exons on the hg19 reference genome (as shown above). include.chr defaults to false: if the BAM file are aligned to a reference sequence with the convention chr1 for chromosomes instead of simply 1 (i.e. the UCSC convention vs. the Ensembl one) you need to set include.chr = TRUE, otherwise the counts will be equal to 0. Note that the data frame with exon locations provided with ExomeDepth uses the Ensembl location (i.e. no chr prefix before the chromosome names) but what matters to set this option is how the BAM files were aligned.

getBAMCounts creates an object of the GRanges class which can easily be converted into a matrix or a data frame (which is the input format for ExomeDepth). An example of GenomicRanges output generated by getBAMCounts is provided in this package (chromosome 1 only to keep the size manageable). Here is how this object could for example be used to obtain a more generic data frame:

```
space start
                 end width
                                      names
                                                    GC Exome1 Exome2 Exome3 Exome4
                                                             0
                                                                    0
                                                                            0
1
      1 12012 12058

#### 2.2 Counts for chromosome X

> data(exons.hg19.X)

Calling CNVs on the X chromosome can create issues if the exome sample of interest and the reference exome samples it is being compared to (what I call the aggregate reference) are not gender matched. For this reason the chromosome X exonic regions are not included by default in the data frame exons.hg19, mostly to avoid users getting low quality CNV calls because of this issue. However, loading the same dataset in R also brings another object called exons.hg19.X that containts the chromosome X exons.

name

238055	X	170411	170514	NCRNA00108-001_1
238056	X	171605	171759	NCRNA00108-001_2
238057	Х	172683	172713	NCRNA00108-001_3
238058	X	192992	193062	PLCXD1-201_1
238059	X	198150	198352	PLCXD1-201_2
238060	Х	200835	200982	PLCXD1-201_3

This object can be used to generate CNV counts and further down the line CNV calls, in the same way as exons.hg19. While this is not really necessary, I would recommend calling CNV on the X separately from the autosomes. Also make sure that the genders are matched properly (i.e. do not use male as a reference for female samples and vice versa).

## 3 Load an example dataset

We have already loaded a dataset of chromosome 1 data for four exome samples. We run a first test to make sure that the model can be fitted properly. Note the use of the subset.for.speed option that subsets some rows purely to speed up this computation.

## 4 Build the most appropriate reference set

A key idea behing ExomeDepth is that each exome should not be compared to all other exomes but rather to an optimized set of exomes that are well correlated with that exome. This is what I call the optimized aggregate reference set, which is optimized for each exome sample. So the first step is to select the most appropriate reference sample. This step is demonstrated below.

Note that the drop = FALSE option is just used in case the reference set contains a single sample. If this is the case, it makes sure that the subsetted object is a data frame, not a numeric vector.

## 5 CNV calling

4

575

576

deletion

> all.exons <- new('ExomeDepth',

test = my.test,

Now the following step is the longest one as the beta-binomial model is applied to the full set of exons:

reference = my.reference.selected,

```
formula = 'cbind(test, reference) ~ 1')
   We can now call the CNV by running the underlying hidden Markov model:
> all.exons <- CallCNVs(x = all.exons,</pre>
                         transition.probability = 10^-4,
                         chromosome = ExomeCount.dafr$space,
                         start = ExomeCount.dafr$start,
                         end = ExomeCount.dafr$end,
                         name = ExomeCount.dafr$names)
Number of hidden states: 3
Number of data points: 26547
Initializing the HMM
Done with the first step of the HMM, now running the trace back
Total number of calls: 23
> head(all.exons@CNV.calls)
                                                    end chromosome
  start.p end.p
                        type nexons
                                        start
       25
                                        89553

                                                                  1
3
      100
            103 duplication
                                   4
                                       743956
                                                 745551
                                                                  1
```

1570002

2 1569583

5	587	591	deleti	ion	5	1592941	1603069	)	1
6	2324	2327	deleti	ion	4	12976452	12980570	)	1
			id	BF	read	ds.expecte	ed reads.	observed	reads.ratio
1	ch	r1:895	53-91106	12.40		22	24	68	0.304
2	chr1	:324290	0-523834	13.40		38	30	190	0.500
3	chr1	:743956	6-745551	7.67		20	)1	336	1.670
4	chr1:1	569583-	-1570002	5.53		6	88	24	0.353
5	chr1:1	592941-	-1603069	13.90		113	36	434	0.382
6	chr1:129	76452-3	12980570	12.10		78	30	342	0.438

Now the last thing to do is to save it in an easily readable format (csv in this example, which can be opened in excel if needed):

Note that it is probably best to annotate the calls before creating that csv file (see below for annotation tools).

## 6 Ranking the CNV calls by confidence level

ExomeDepth tries to be quite aggressive to call CNVs. Therefore the number of calls may be relatively high compared to other tools that try to accomplish the same task. One important information is the BF column, which stands for Bayes factor. It quantifies the statistical support for each CNV. It is in fact the log10 of the likelihood ratio of data for the CNV call divided by the null (normal copy number). The higher that number, the more confident once can be about the presence of a CNV. While it is difficult to give an ideal threshold, and for short exons the Bayes Factor are bound to be unconvincing, the most obvious large calls should be easily flagged by ranking them according to this quantity.

> head(all.exons@CNV.calls[ order ( all.exons@CNV.calls\$BF, decreasing = TRUE),])

	start.p	end.p	type	nexons	start	end	chromoso	me

### 7 Better annotation of CNV calls

Much can be done to annotate CNV calls and this is an open problem. While this is a work in progress, I have started adding basic options. Importantly, the key function uses the more recent syntax from the package GenomicRanges. Hence the function will only return a warning and not add the annotations if you use a version of GenomicRanges prior to 1.8.10. The best way to upgrade is probably to use R 2.15.0 or later and let Bioconductor scripts do the install for you. If you use R 2.14 or earlier the annotation steps described below will probably only return a warning and not annotate the calls.

Perhaps the most useful step is to identify the overlap with a set of common CNVs identified in Conrad et al, Nature 2010. If one is looking for rare CNVs, these should probably be filtered out. The first step is to load these reference data from Conrad et al. To make things as practical as possible, these data are now available as part of ExomeDepth.

- > data(Conrad.hg19)
- > head(Conrad.hg19.common.CNVs)

GRanges with 6 ranges and 1 metadata column:

```

seqlengths:

Then one can use this information to annotate our CNV calls with the function AnnotateExtra.

The min.overlap argument set to 0.5 requires that the Conrad reference call overlaps at least 50% of our CNV calls to declare an overlap. The column.name argument simply defines the name of the column that will store the overlap information. The outcome of this procedure can be checked with:

#### > print(head(all.exons@CNV.calls))

```

I have processed the Conrad et al data in the GRanges format. Potentially any other reference dataset could be converted as well. See for example the exon information:

```
exons.hg19.GRanges <- GRanges(seqnames = exons.hg19$chromosome,
                                    IRanges(start=exons.hg19$start,end=exons.hg19$end),
                                   names = exons.hg19$name)
  all.exons <- AnnotateExtra(x = all.exons,
                              reference.annotation = exons.hg19.GRanges,
                              min.overlap = 0.0001,
                              column.name = 'exons.hg19')
 all.exons@CNV.calls[3:6,]
  start.p end.p
                                                   end chromosome
                        type nexons

```

This time I report any overlap with an exon by specifying a value close to 0 in the min.overlap argument. Note the metadata column names which MUST be specified for the annotation to work properly.

## 8 A visual example

The ExomeDepth object includes a plot function. This function shows the ratio between observed and expected read depth. The 95% confidence interval is marked by a grey shaded area. Here we use a common CNV located in the RHD gene as an example. We can see that the individual in question has more copies than the average (in fact two functional copies of RHD, which corresponds to rhesus positive).

## 9 How to loop over the multiple samples

A FAQ is a way to deal with a set of a significant number of exomes, i.e. how to loop over all of them using ExomeDepth. This can be done with a loop. I show below an example of how I would code things. The code is not executed in the vignette to save time when building the package, but it can give some hints to users who do not have extensive experience with R.

```
n.bins.reduced = 10000)
+
   my.reference.selected <- apply(X = ExomeCount.mat[, my.choice$reference.choice, drop = FALSE],</pre>
                                   MAR = 1,
+
                                   FUN = sum)
+
   message('Now creating the ExomeDepth object')
    all.exons <- new('ExomeDepth',
                     test = ExomeCount.mat[,i],
                     reference = my.reference.selected,
+
                     formula = 'cbind(test, reference) ~ 1')
+ ############ Now call the CNVs
   all.exons <- CallCNVs(x = all.exons,
+
                          transition.probability = 10^-4,
+
                          chromosome = ExomeCount.dafr$space,
                          start = ExomeCount.dafr$start,
                          end = ExomeCount.dafr$end,
                          name = ExomeCount.dafr$names)
+ ##################### Now annotate the ExomeDepth object
   all.exons <- AnnotateExtra(x = all.exons,
                               reference.annotation = Conrad.hg19.common.CNVs,
+
                               min.overlap = 0.5,
                               column.name = 'Conrad.hg19')
   all.exons <- AnnotateExtra(x = all.exons,
                               reference.annotation = exons.hg19.GRanges,
+
                               min.overlap = 0.0001,
                               column.name = 'exons.hg19')
+
+
   output.file <- paste('Exome_', i, 'csv', sep = '')</pre>
    write.csv(file = output.file, x = all.exons@CNV.calls, row.names = FALSE)
+
+ }
